Introduction

Week 1: Scientific method

Week 2: Causal theorising

Week 3: Research design

Week 4: Concepts and measurement

Week 5: Surveys and sampling

Upon successful completion, students will have the knowledge and skills to:

1. explain the complexity of contemporary politics from the perspective of solid research design and empirical analysis;
2. apply a range of methodological approaches by which to analyse such issues;
3. generate, explain, and visualise descriptive statistics and basic inferential statistics for political phenomena using a statistical software package; and
4. apply conceptual and analytical tools to a political phenomenon at a higher level of study or in a professional working environment.

$$Y = \alpha + \beta X + \epsilon + \varepsilon$$

There is often an easier map to quantitative analysis than qualitative analysis.

Source: <https://static1.scrdn.com/wordpress/wp-content/uploads/2020/05/Elmo-Flames-Meme.jpg>

$$Y = \alpha + \beta X + \epsilon + \varepsilon$$

Where:

Y is the **outcome** you are trying to explain.

X is the main **explanatory** variable.

α (alpha) is the intercept.

β (beta) is the estimated relationship between X and Y.

ϵ is the systematic error.

ε is the random error.

We will be coming back to this equation in a few weeks, but first we need to start by learning about our main **cause (X)** and **outcome (Y)** variables.

What can **descriptive inference** tell us that causal inference cannot?

What are the basic **descriptive statistics**?

1

Political scientists spend much more time thinking about **causal inference** and **data** analysis than they think about **conceptualising** and **describing** their causes (X's) and outcomes (Y's).

However, the former is of limited utility without the latter.

Image source: <https://imgflip.com/mememtemplate/57007095/Wrong-tool-for-the-job>

2

Descriptive inference

Most people use real-world data without thinking about **how they are generated** and **whether they capture what they think they do**.

2

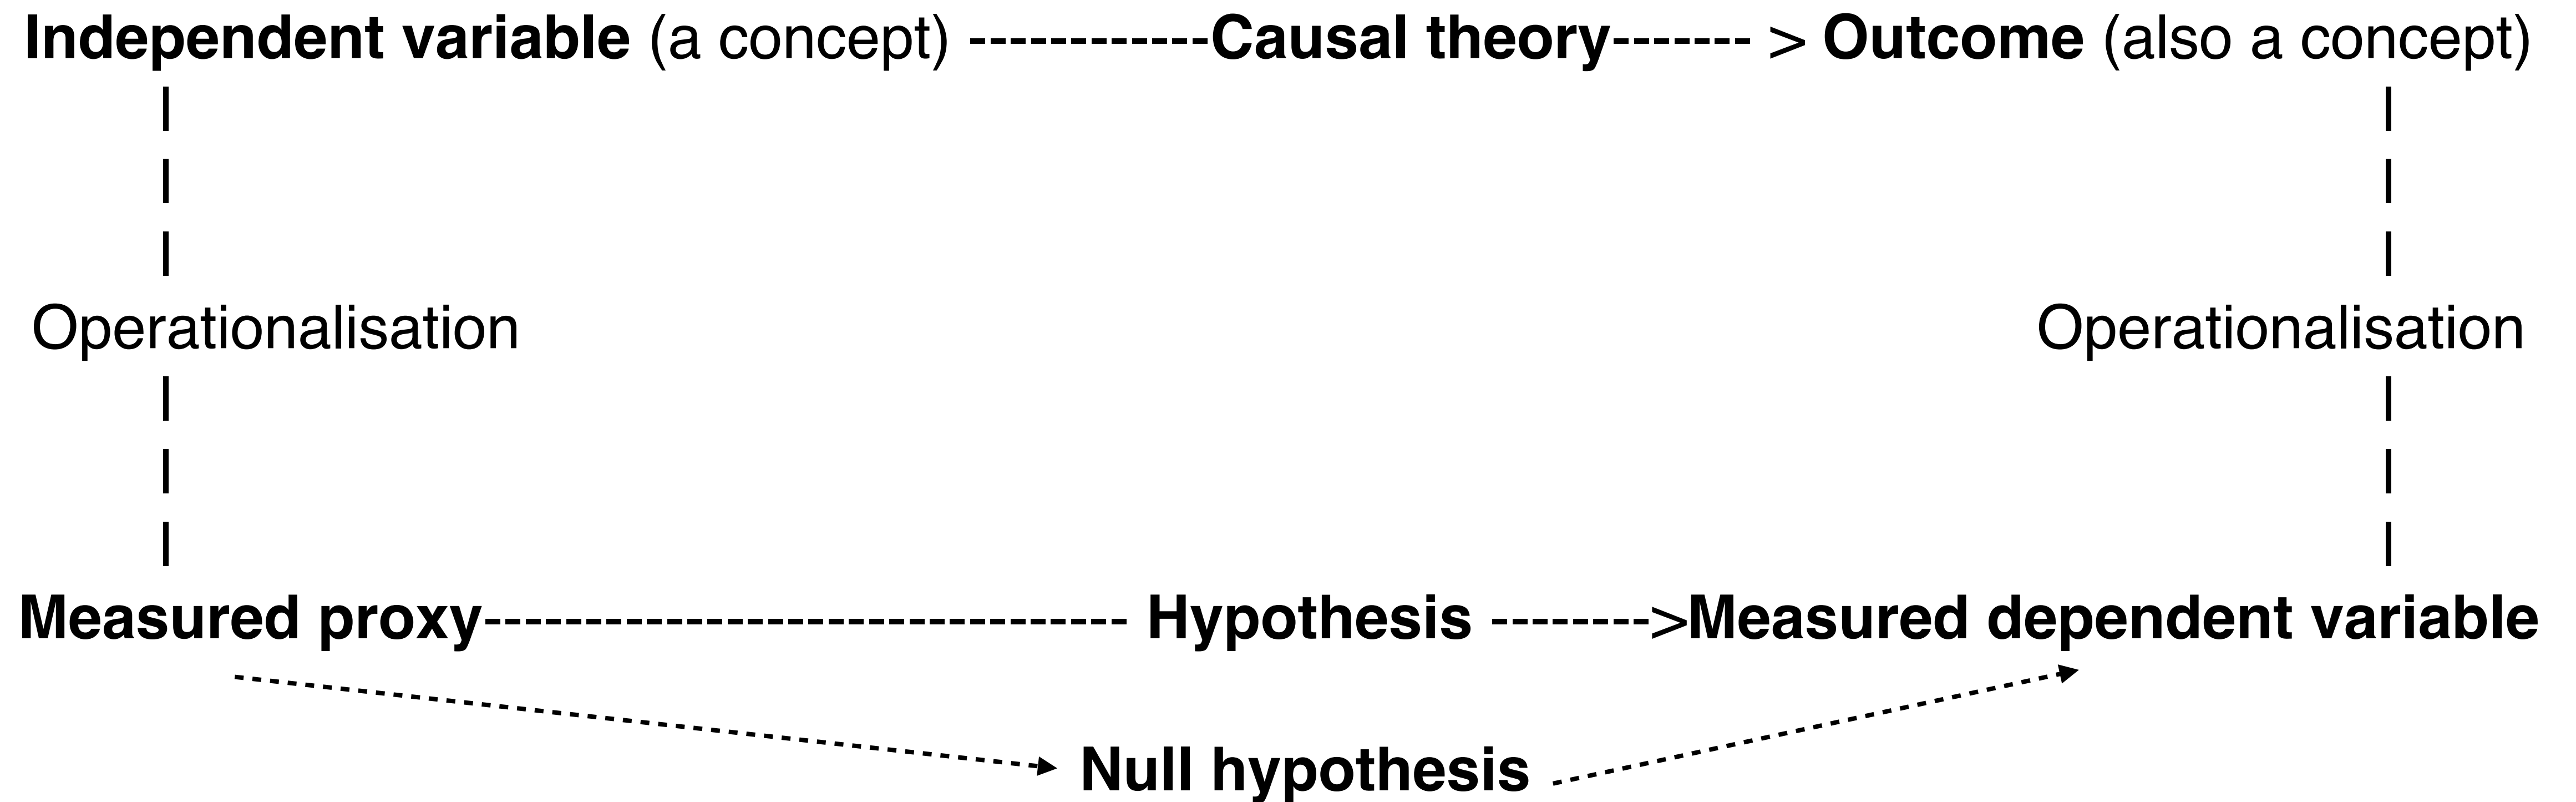

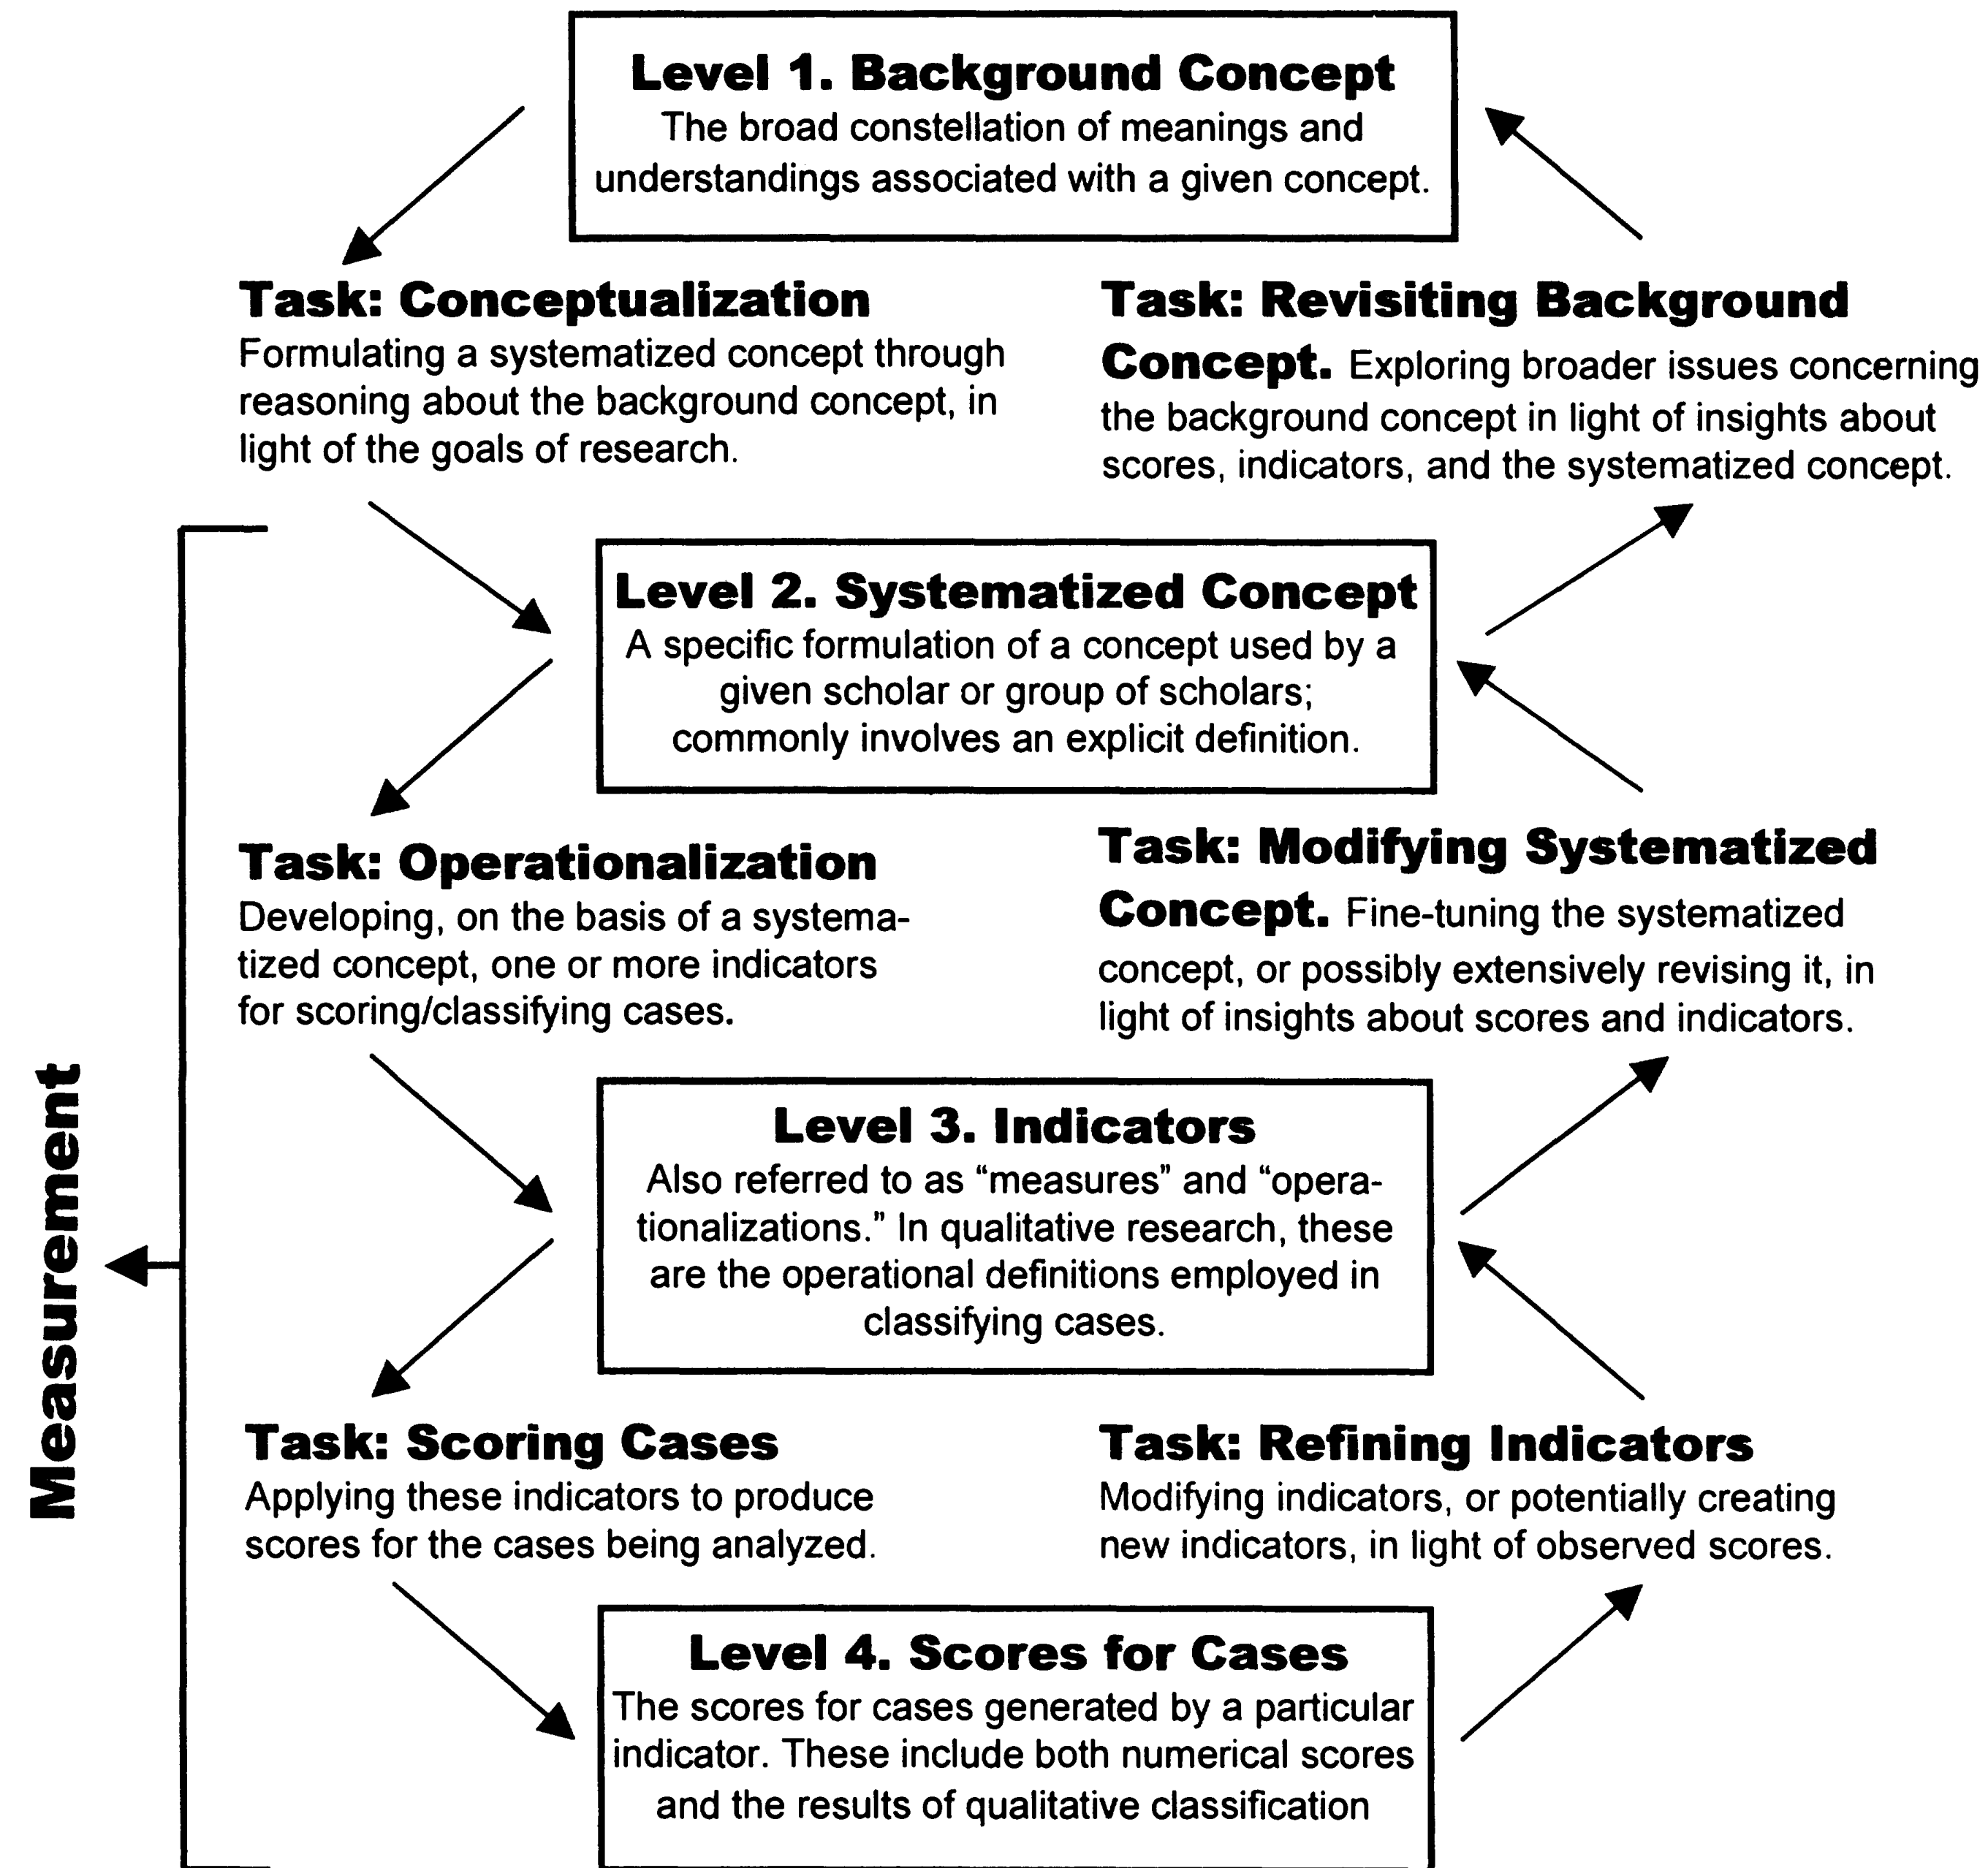

FIGURE 1. Conceptualization and Measurement: Levels and Tasks

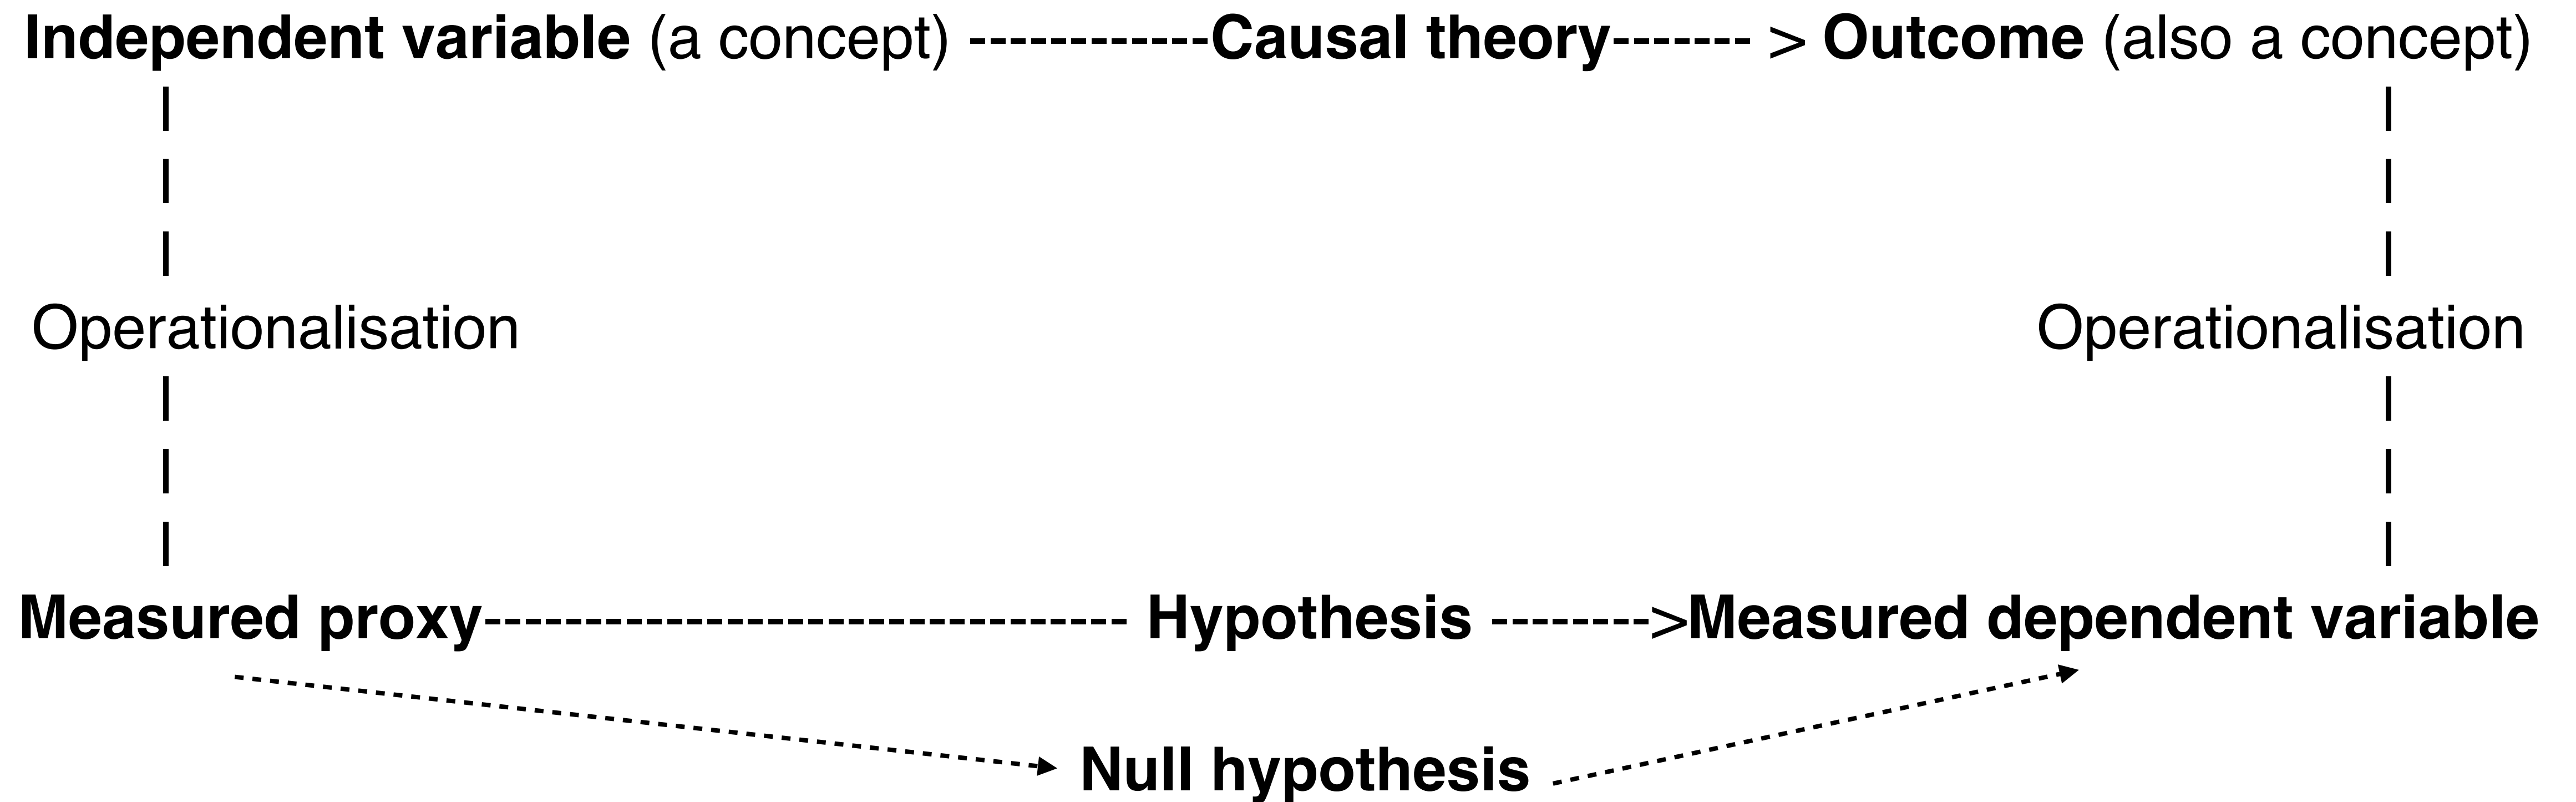

“A **descriptive argument** describes some aspect of the world.

In doing so it aims to answer **what questions** (e.g. when, whom, out of what, in what manner) about a phenomenon or a set of phenomena.”

(Gerring 2012: 722, emphasis added)

2

As Gerring (2012) makes clear, most current political science research focuses on **causal inference** rather than **description**.

However, description and causality are intimately related and can often overlap.

First, we need to understand the ***what*** before we can ask ***why***.

Measuring state capacity: Theoretical and empirical implications for the study of civil conflict

Cullen S Hendrix

Department of Political Science, University of North Texas; and Centre for the Study of Civil War, International Peace Research Institute, Oslo (PRIO)

Abstract

This article identifies and addresses key conceptual and measurement issues raised by measures of state capacity in studies of civil conflict. First, it reviews competing definitions and operationalizations of state capacity, focusing specifically on those that emphasize (1) military capacity, (2) bureaucratic administrative capacity, and (3) the quality and coherence of political institutions. Second, it critically assesses these measures on the basis of construct validity, focusing attention on whether they accurately capture the theoretical concept of state capacity, and whether they allow the researcher to differentiate between competing causal mechanisms. Third, it employs principal factor analysis to identify the underlying dimensionality of 15 different operationalizations of state capacity. State capacity is characterized by low dimensionality, with three factors – or dimensions of state capacity – explaining over 90% of the variance in the 15 measures. While the first factor, *rational legality*, captures bureaucratic and administrative capacity, the second, *rentier-autocraticness*, and third, *neopatrimoniality*, capture aspects of state capacity that cut across theoretical categories. The article concludes by suggesting a multivariate approach to modeling state capacity, and that (1) survey measures of bureaucratic quality, and (2) tax capacity are the most theoretically and empirically justified.

Keywords

civil conflict, construct validity, factor analysis, state capacity

Introduction

State capacity is a quality conspicuous both in its absence and presence but difficult to define. Despite its importance for the study of inter- and intrastate conflict, state capacity remains a concept in search of precise definition and measurement. The various contributions to this special issue, and the works on which they build, may advance our understanding of the causes of civil conflict, but they represent different notions and operationalizations of the concept. The purpose of my contribution is threefold: first, to review the definitions and operationalizations of state capacity in the civil war literature; second, to assess their validity; and third, to determine whether they point to a common quality – or set of qualities – that can inform work relating state capacity to conflict.

Within the civil war literature, interest in state capacity has coincided with a turn away from a debate over motive (whether economic greed or societal grievance) and toward the political opportunity structure that affects potential rebels' decisions to fight. The political opportunity model (Tilly, 1978) places state capacity at the center. The decision to rebel takes into account the government's capacity for repression and accommodation. If the state is capable of repressing, then the likelihood of capture will be higher and rebellion will be

less likely. If the state is capable of accommodating grievances via institutionalized channels, such as redistribution, the granting of autonomy rights, or the incorporation of dissident movements within the party system, then the motivation for violent rebellion will be lessened and conflict will be less likely.

In either the repressive or accommodative response scenario, state capacity is central. For a state to repress, it must identify potential rebels and apply coercion. For a state to accommodate, it must redistribute resources and power. Yet these are two very different notions of state capacity. The articles that comprise this special issue use at least seven different definitions and operationalizations of the concept, with another eight playing prominent roles in the literatures on conflict and economic development. It is an open question, however, whether these measures capture distinct theoretical concepts or vectors of variance.

This article addresses three theoretical definitions of state capacity: military power, bureaucratic/administrative capacity, and the quality and coherence of political institutions. Decisions about how to best operationalize the concept of state

Are political science topics just different?

Fig. 4. The disciplines compared, 1980–99

Notes: The share of all articles (not reviews, editorials, or other matter) within top journals in various disciplines mentioning at least one of the following search terms: *causation*, *causality*, or *causal*. The denominator of the ratio – total articles within each stipulated period – was provided by JSTOR’s data support team and is available upon request. Searches conducted using the JSTOR on-line search function in November, 2008.

Political Science (PO) journals include: *American Political Science Review*, *American Journal of Political Science*, and *World Politics*. Sociology (SO) journals include: *American Journal of Sociology*, *American Sociological Review*, and *Social Forces*. Economics (EC) journals include: *American Economic Review*, *Quarterly Journal of Economics*, and *Journal of Political Economy*. Psychology (PSY) journals include the *American Journal of Psychology*. (The eight other psychology journals in the JSTOR collection are subfield journals, and thus inappropriate for our purpose.) Anthropology (ANT) journals include: *American Anthropologist*, *American Ethnologist*, and *Journal of the Royal Anthropological Institute/Man*. Natural science (NAT) journals include all journals listed in JSTOR under the following disciplinary categories: Biological Sciences, Botany and Plant Sciences, Developmental and Cell Biology, Ecology and Evolutionary Biology, General Science, Health Sciences, Mathematics, and Zoology (N = 432).

Concepts—Economic output, population, democracy

Measurement—GDP, Polity, V-Dem

Why is **falsifying** descriptive arguments so hard?

Describing a concept: What is democracy and how should we measure it?

Causal argument: Does democracy increase the chance of victory in war?

“A description of even the smallest slice of reality can **never be exhaustive.**”

(Max Weber 1905, quoted in Gerring 2012: 738)

“Any phenomenon of significance to social science is likely to call up **multiple words**, and **multiple definitions** of those words.”

(Gerring 2012: 738).

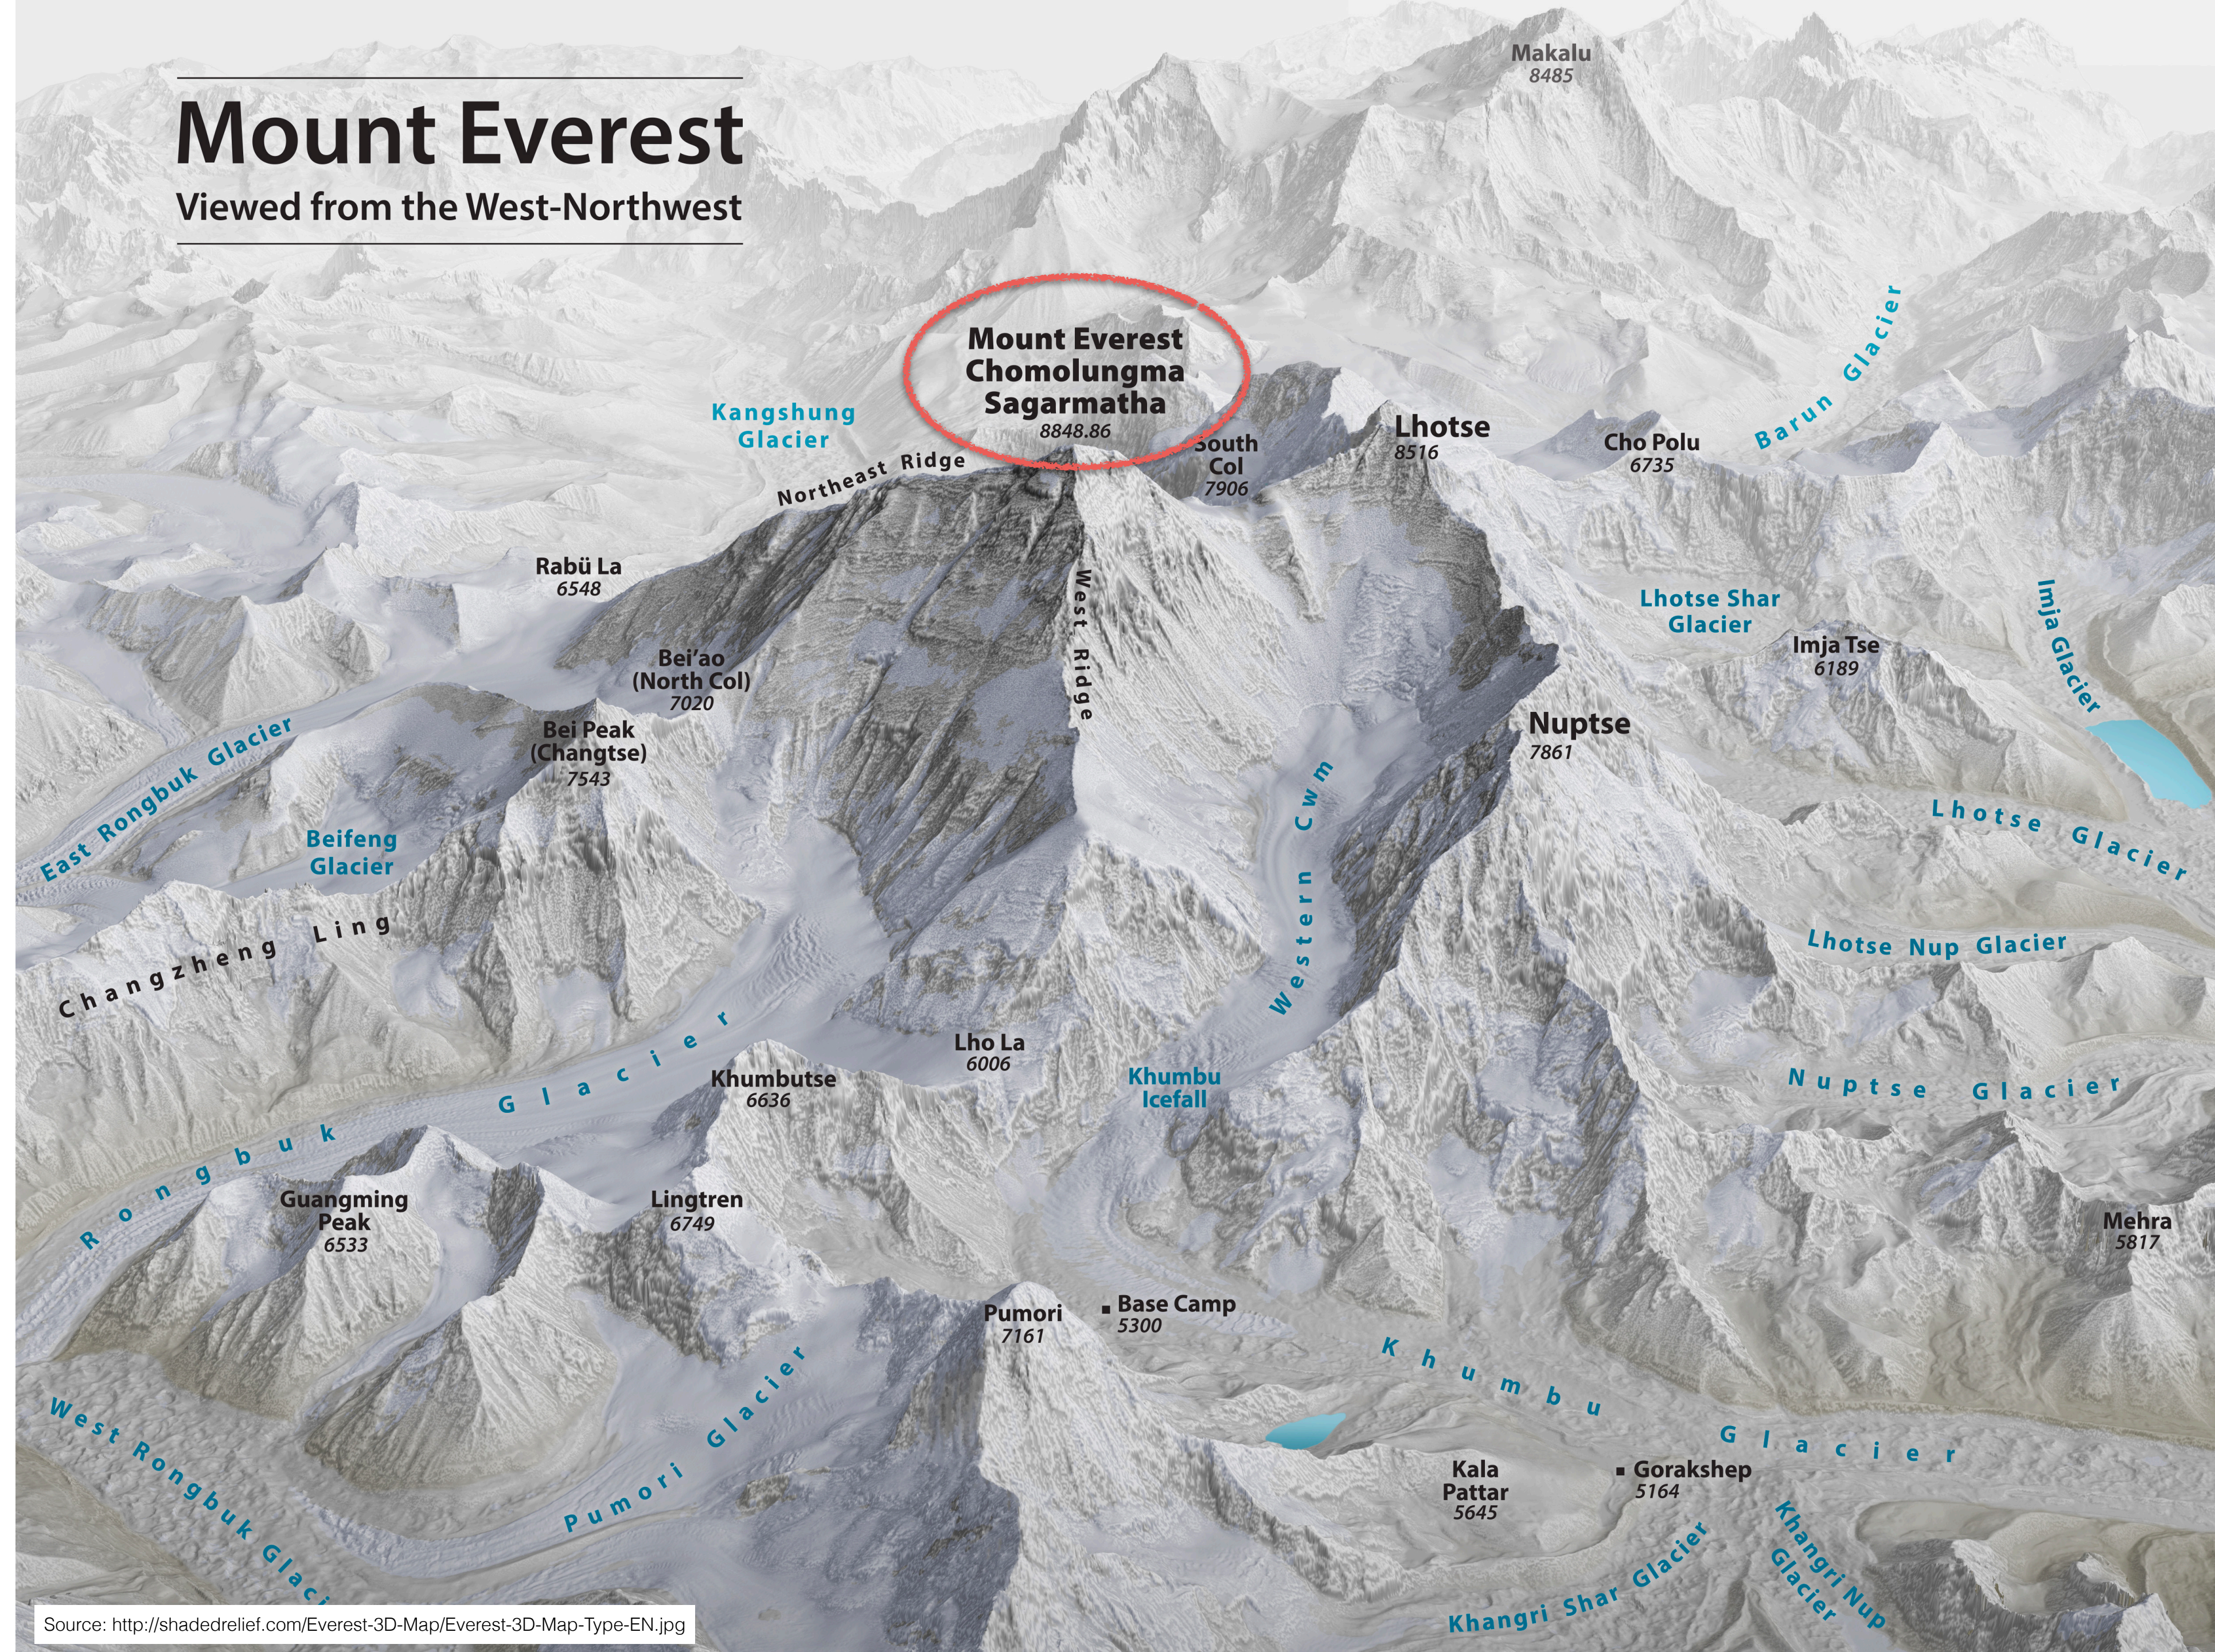

“To describe something is to **assert its ultimate value**,”

(Gerring 2012: 740)

Therefore, descriptions include an inherent **subjectivity**.

Robustness checks!

We will come back to these techniques in a few weeks.

Political Analysis, 11:2(R)

Correlation versus Interchangeability: The Limited Robustness of Empirical Findings on Democracy using Highly Correlated Datasets

Gretchen Casper
Penn State University

Claudiu Tufis
Penn State University

This article shows that highly correlated measures can produce different results. We identify a democratization model from the literature and test it in over 120 countries from 1951-1992. Then, we check whether the results are robust regarding measures of democracy, time periods, and levels of development. The findings show that measures do matter: while some of the findings are robust, most of them are not. This explains, in part, why the debates on democracy have continued rather than been resolved. More importantly, it underscores the need for more careful use of measures and further testing to increase confidence in the findings. Scholars in comparative politics increasingly are drawn to large-N statistical analyses, often using datasets collected by others. As in any field, we show how they must be careful in choosing the most appropriate measures for their study, without assuming that any correlated measure will do.

1 Introduction

Democracy, like representation or power, is a basic concept in political science that is inherently difficult to measure. While different scholars have accepted different tradeoffs between consistency and operationalization when constructing their measures, resulting in a range of different measures of democracy, their measures correlate highly. It would be a reasonable assumption for a researcher to treat the measures interchangeably, selecting one that best fits the time period, number of countries, or particular variables that she was interested in. However, as we show in this article, despite high correlations, the use of these different measures can produce different results

Authors' note: We acknowledge generous advice from Frank Baumgartner, Scott Bennett, David Brown, Suzanna DeBoef, Scott Gates, Barbara Geddes, and Quan Li.

How do we measure **latent, unobservable, unmeasurable constructs**?

Democracy

Corruption

Conflict

Development

Skill

Now that we have some ways of describing our topic, let us look at a few ways that we can measure it.

Remember that we should keep in mind **how the data were generated** so as to not try and take away more than we should from the data.

Label: Employment status of survey respondent

Values: “employed” or “unemployed”

Variable type:

(1) ***categorical/nominal*** [*unemployed, employed*]

(2) **ordinal** [*<5 hours, 5-15 hours, 15-35, >35 hours worked per week*]

(3) **continuous/interval/ratio** [time worked last week]

We can put cases into categories based on their values, but we cannot **rank** or order them.

Definition

This variable identifies whether a person uses a language other than English at home and if so, records the main non-English language which is used. The purpose of this variable is to identify the main languages other than English which are used in households across Australia.

Scope

All persons

Categories

Language used at home (LANP) is classified using the [Australian Standard Classification of Languages \(ASCL\), 2016](#). The categories are listed in groups below. The full list is available from the Data downloads on this page.

1 Northern European Languages

2 Southern European Languages

3 Eastern European Languages

4 Southwest and Central Asian Languages

5 Southern Asian Languages

6 Southeast Asian Languages

7 Eastern Asian Languages

8 Australian Indigenous Languages

9 Other Languages

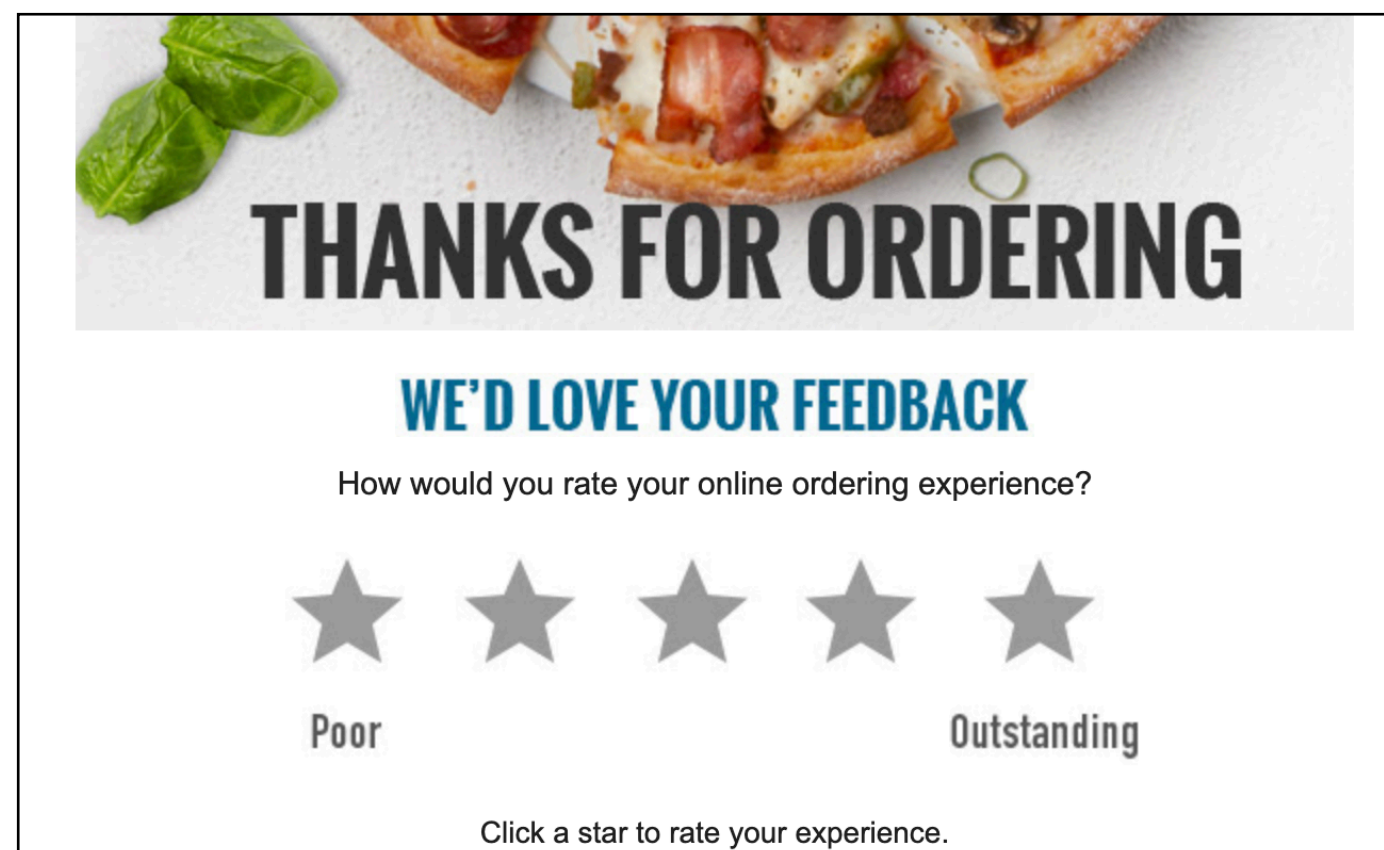

Supplementary codes

Magpie swooping attack percentages across Australia by State 2022

Variables for which cases have values where we **can** make universal ranking distinctions.

If we treat an ordinal variable like a categorical variable, we are acting as if we have less information than we really do.

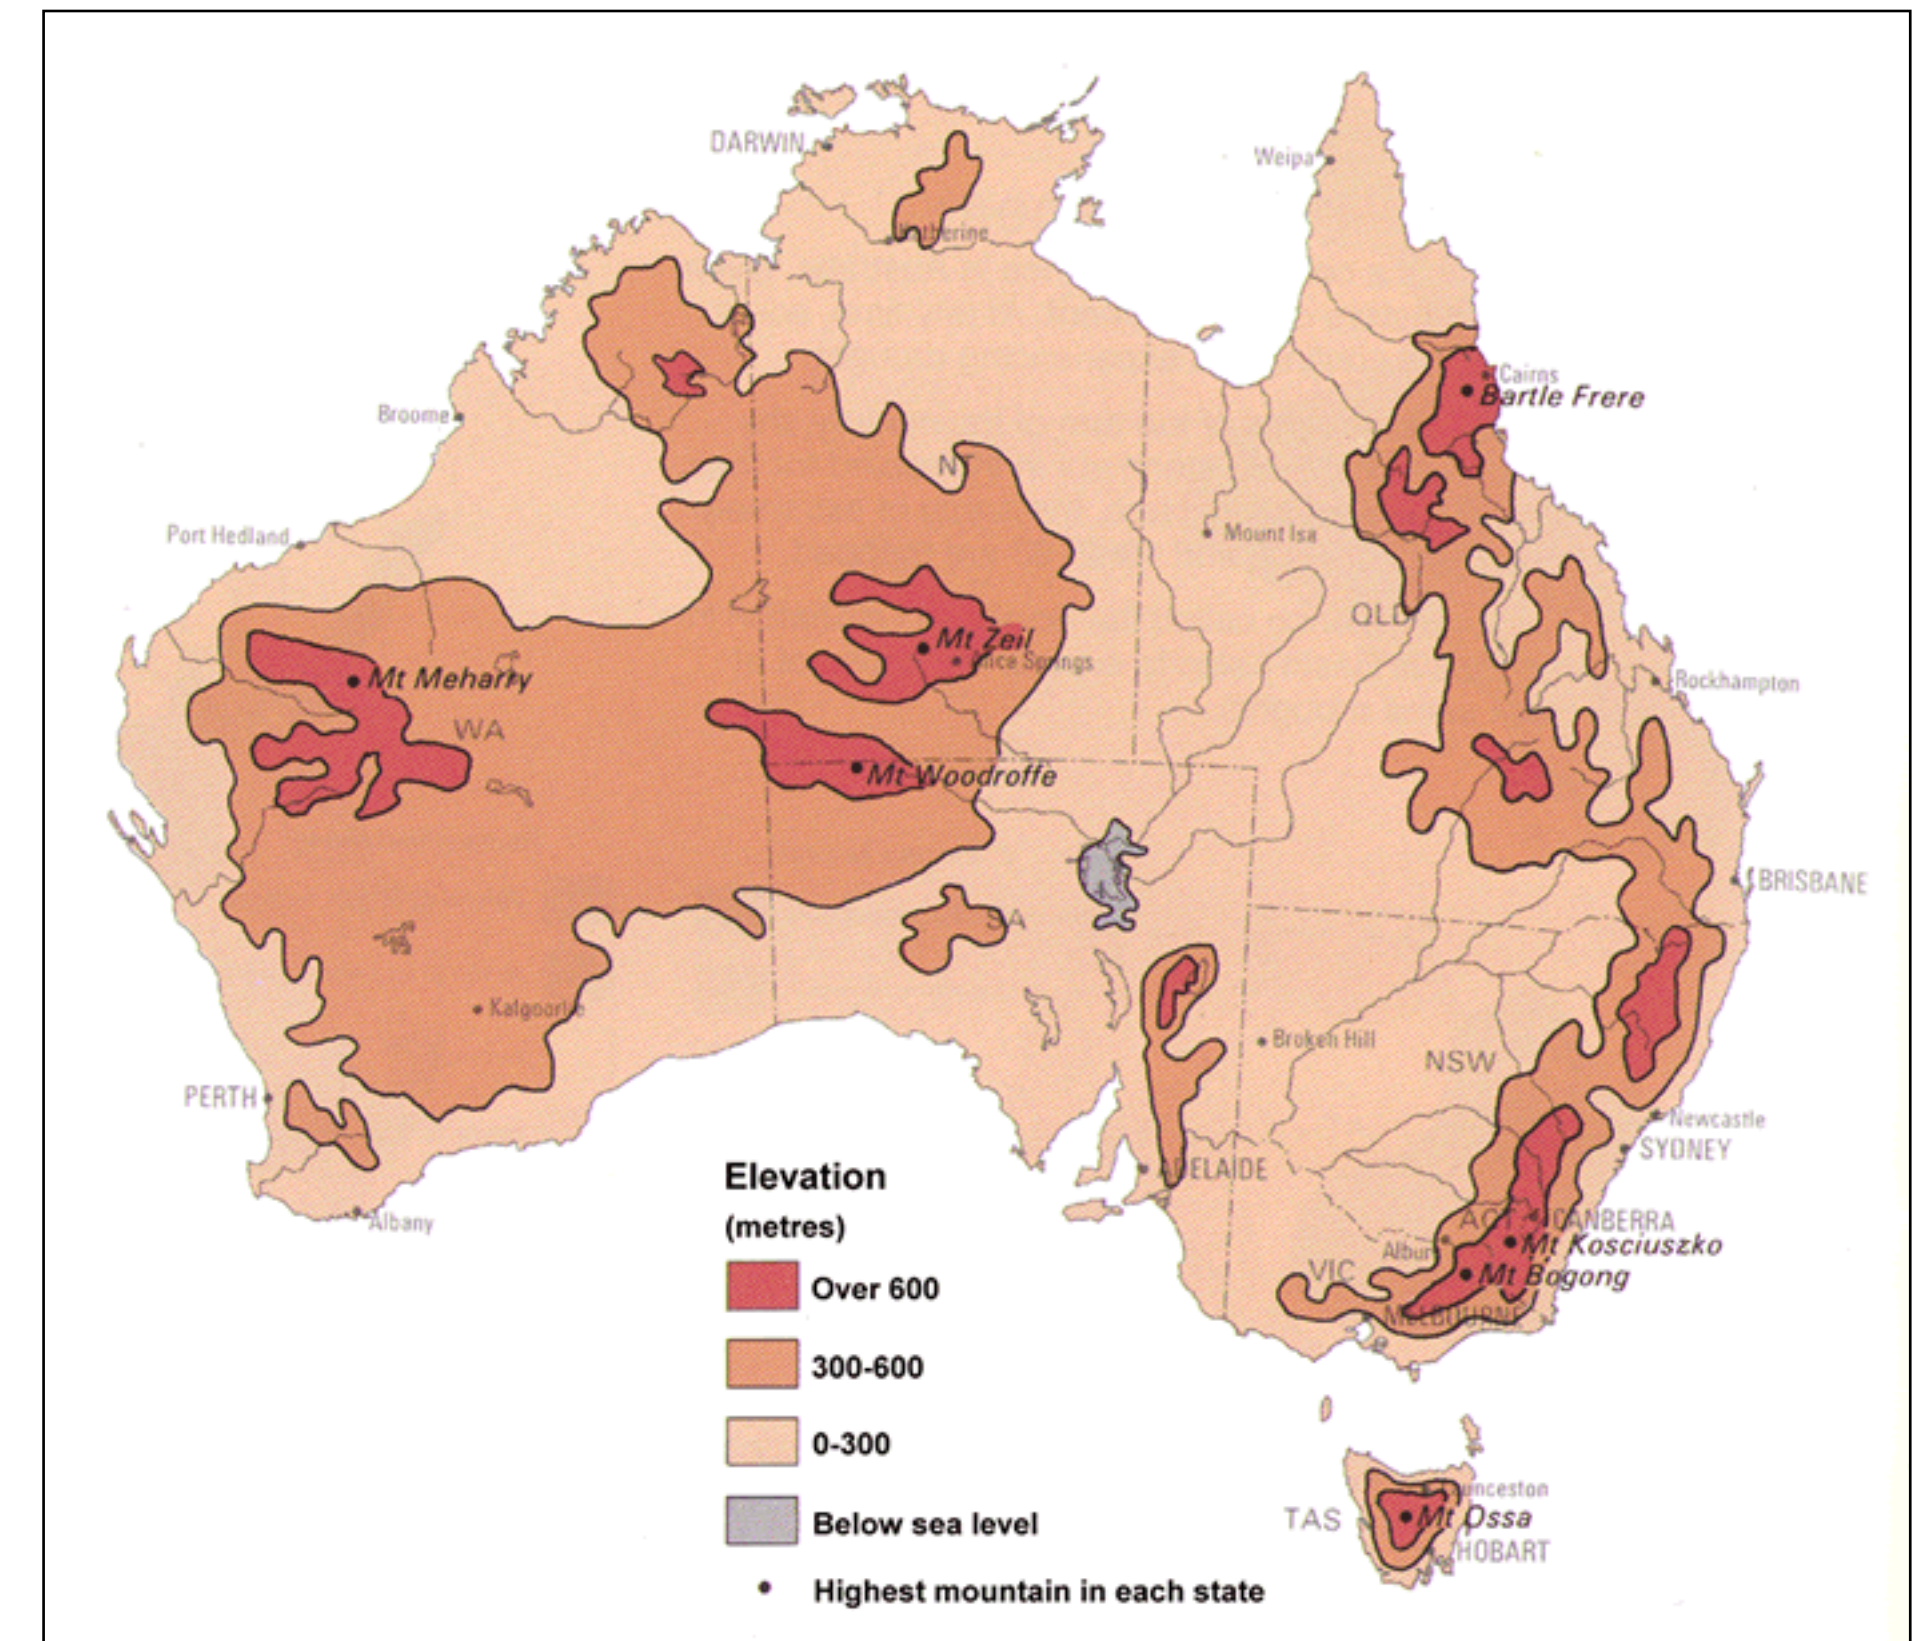

Source: an email I received after recently ordering Dominos.

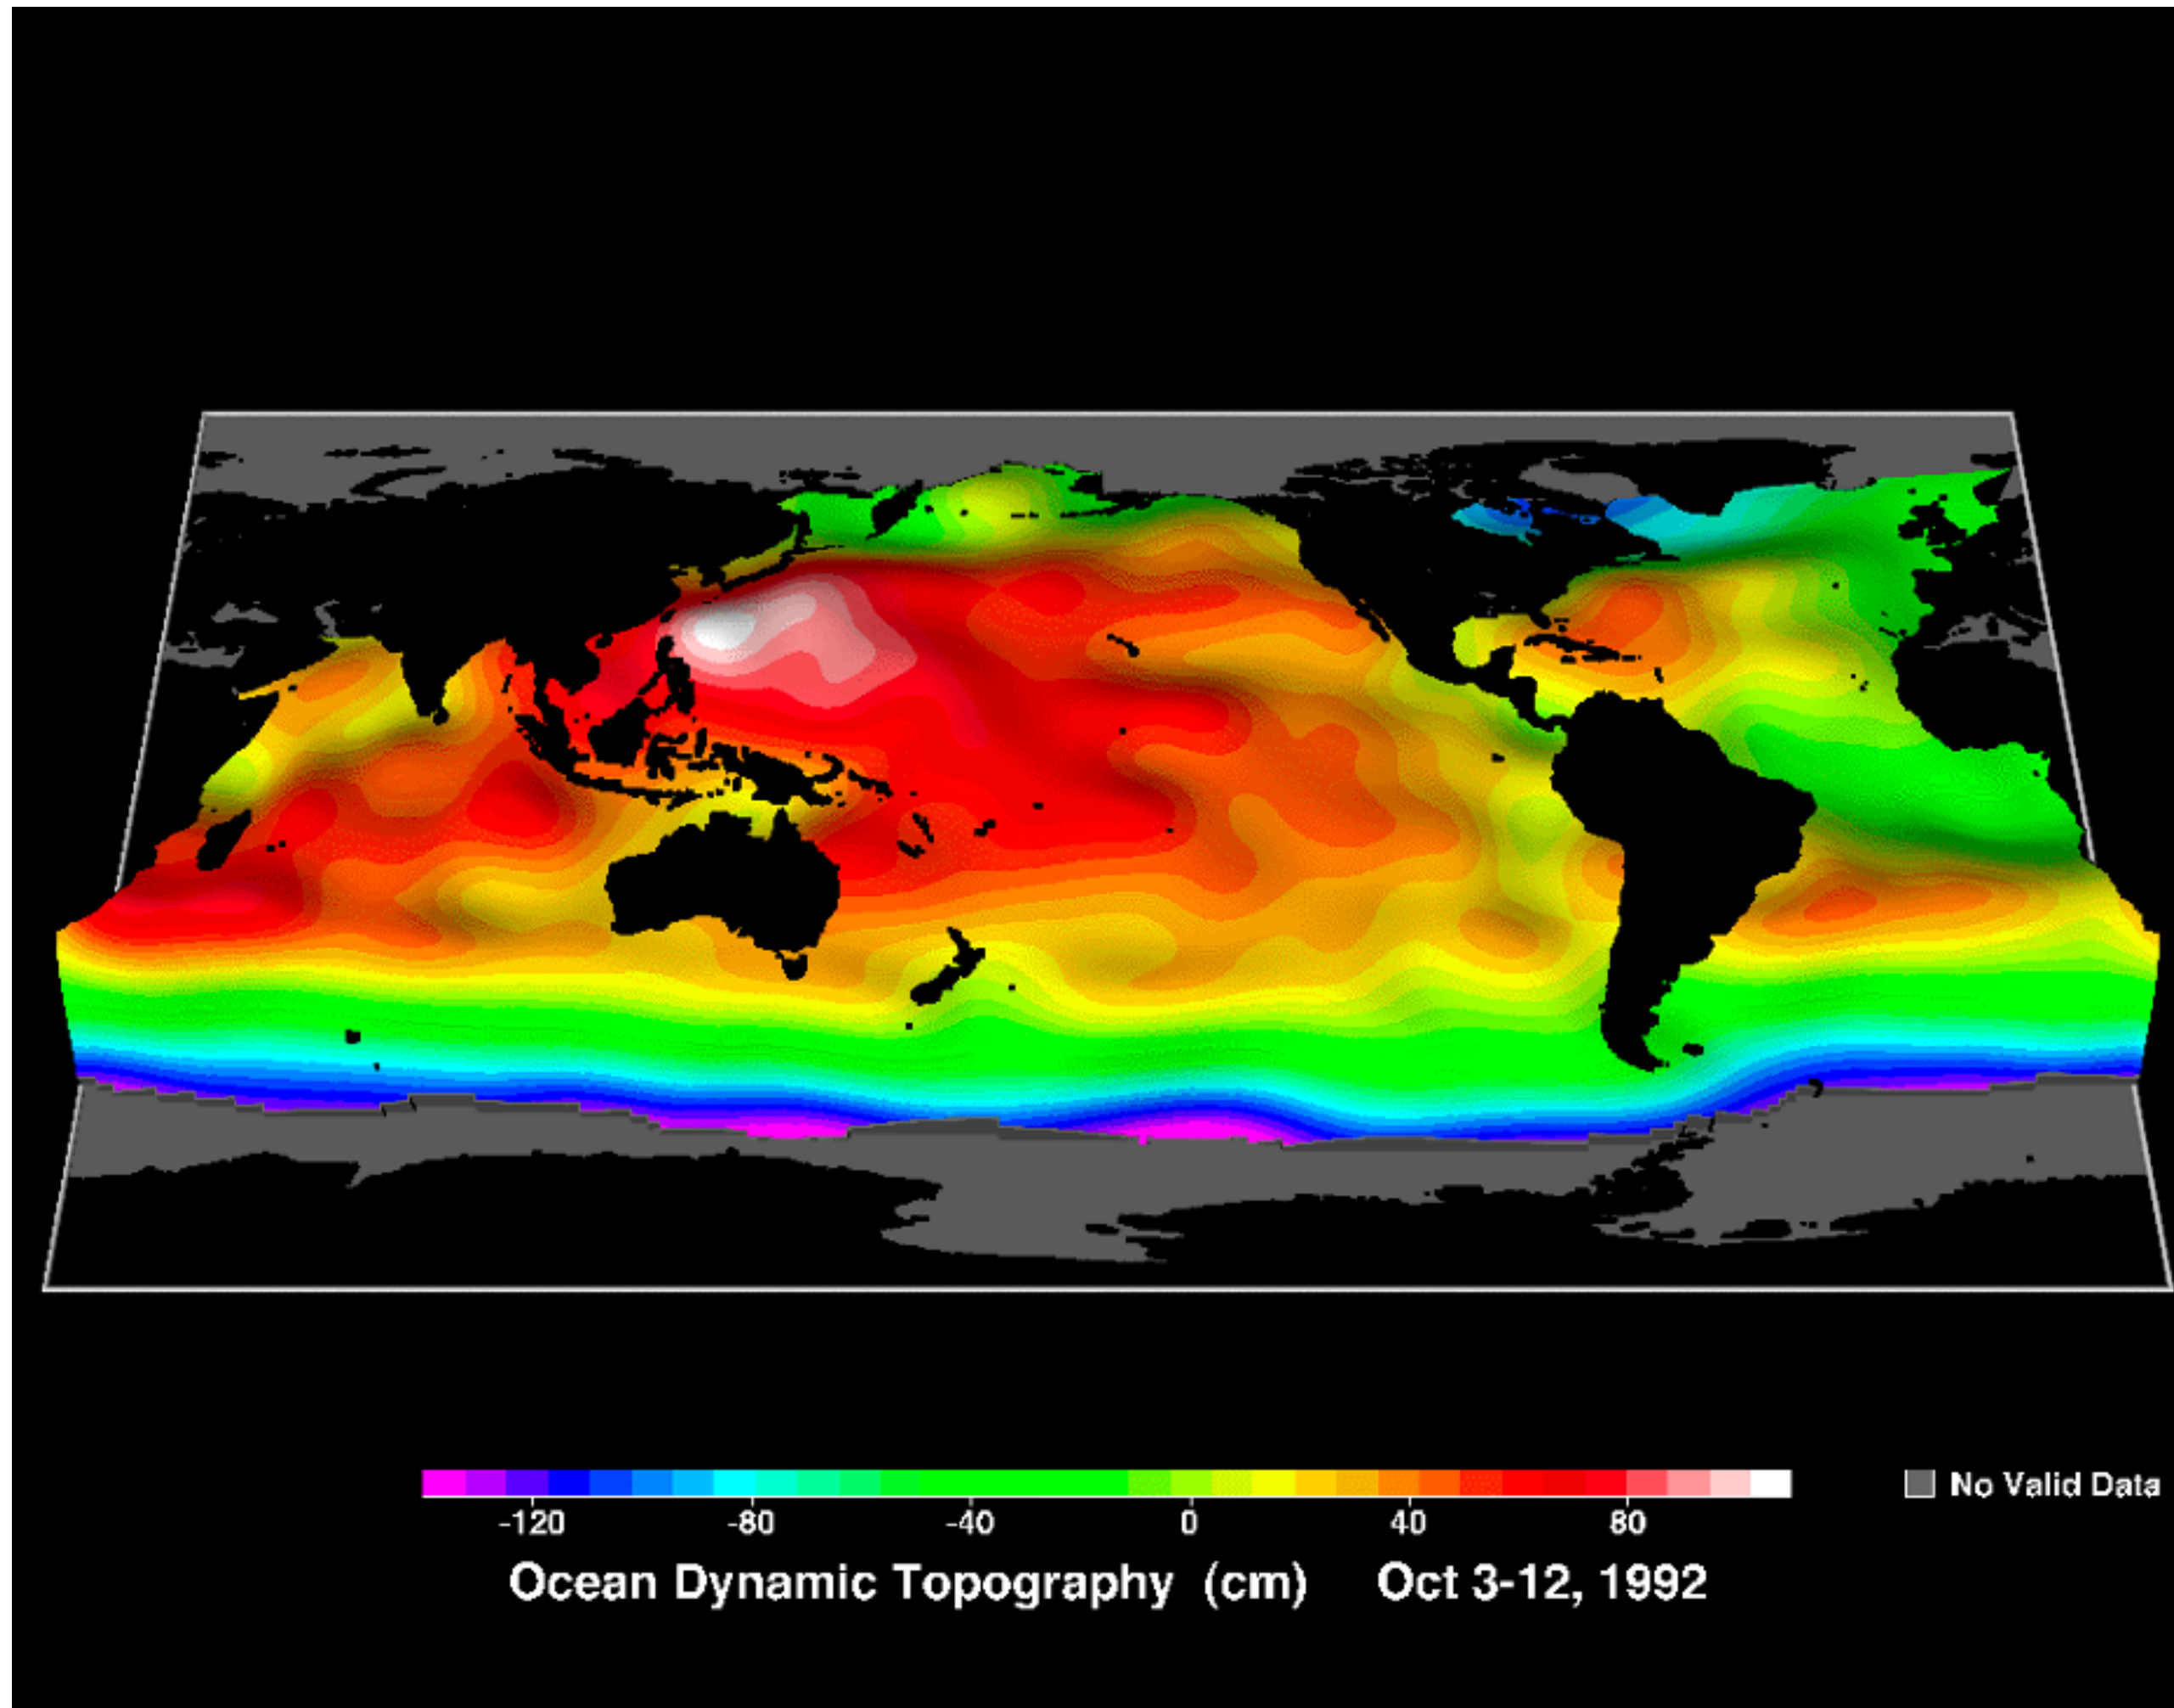

Source: <https://www.abs.gov.au/statistics/people/people-and-communities/snapshot-australia/2021>

Sometimes called **interval** variables or **ratio** variables (if they have a meaningful 0).

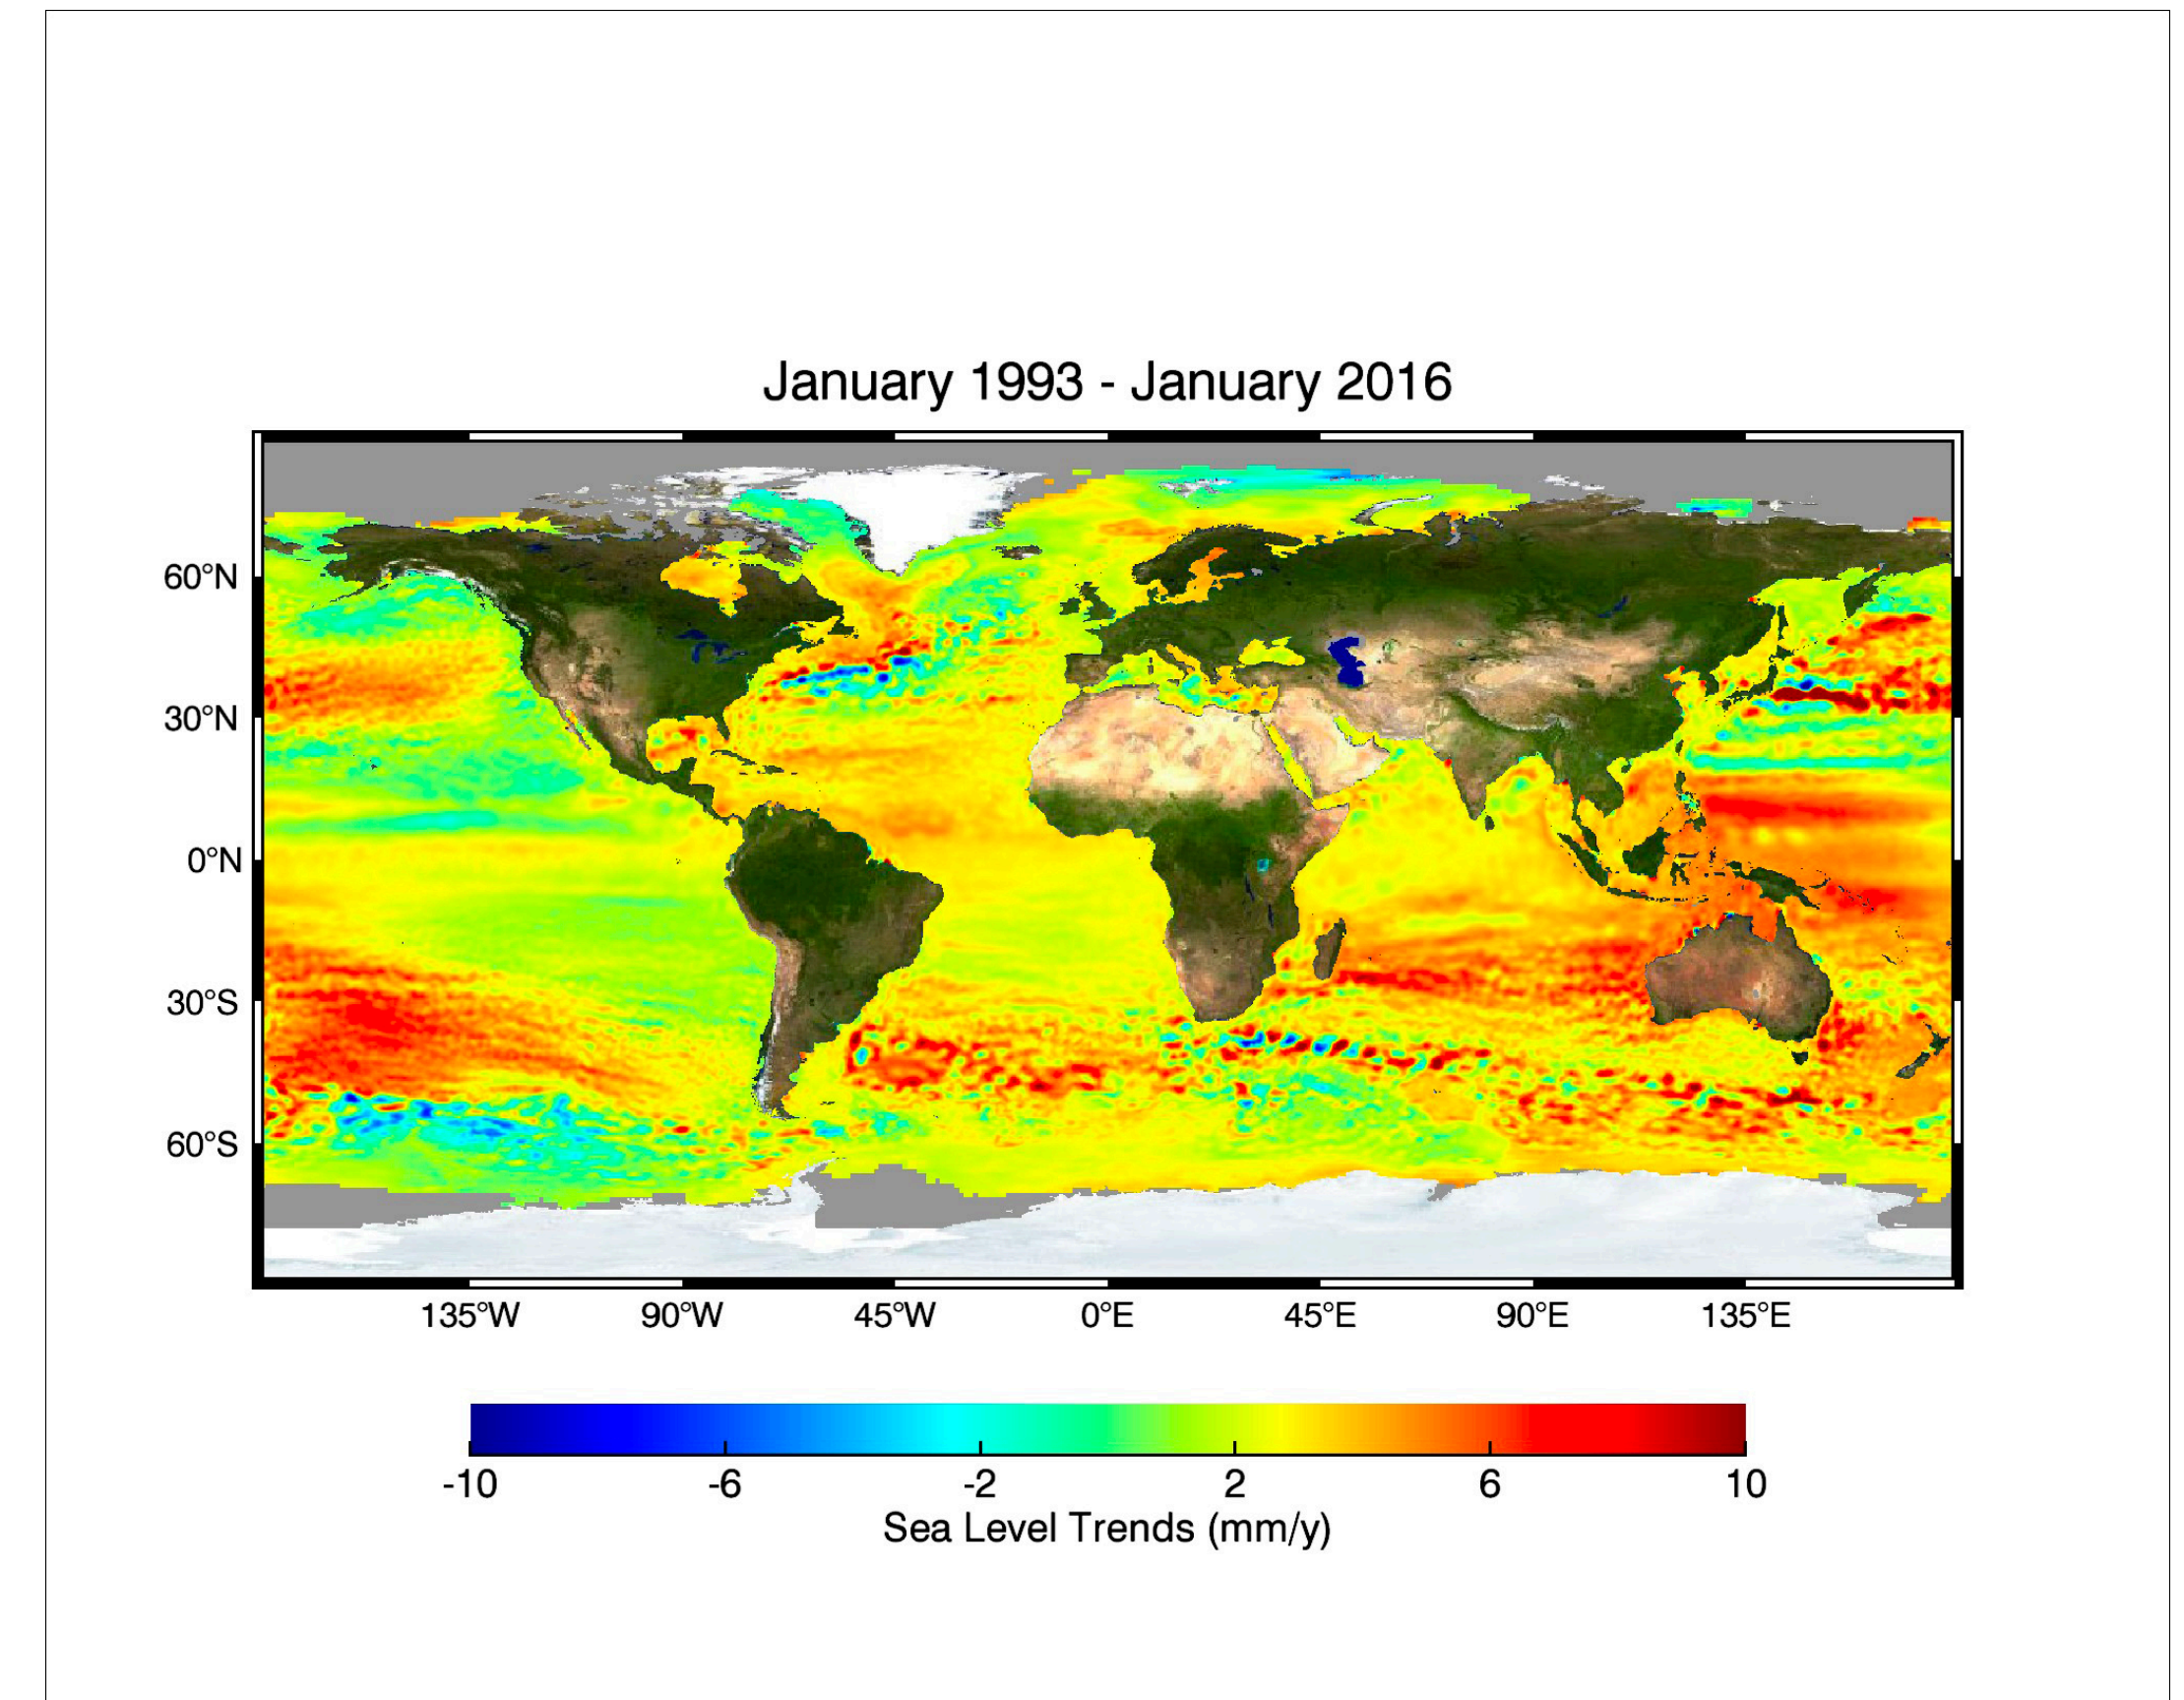

They have **equal unit differences**.

Source: https://www.ga.gov.au/_data/assets/image/0013/12640/GA11759.gif

Source: NASA (<https://climate.nasa.gov/ask-nasa-climate/2990/sea-level-101-what-determines-the-level-of-the-sea/>)

Source: <https://www.weather-atlas.com/weather/images/city/0/3/2332830-1000-75.jpg>

Usually, we focus on the **frequency** distribution of categorical variables with a table, pie charts, or bar graphs.

The only central tendency statistic is the **mode** (the most frequent value).

Quantiles (including percentiles) are also used. They are a measure of **position** within a distribution.

We are primarily interested in the **central tendency** and the **distribution** of values around this central tendency.

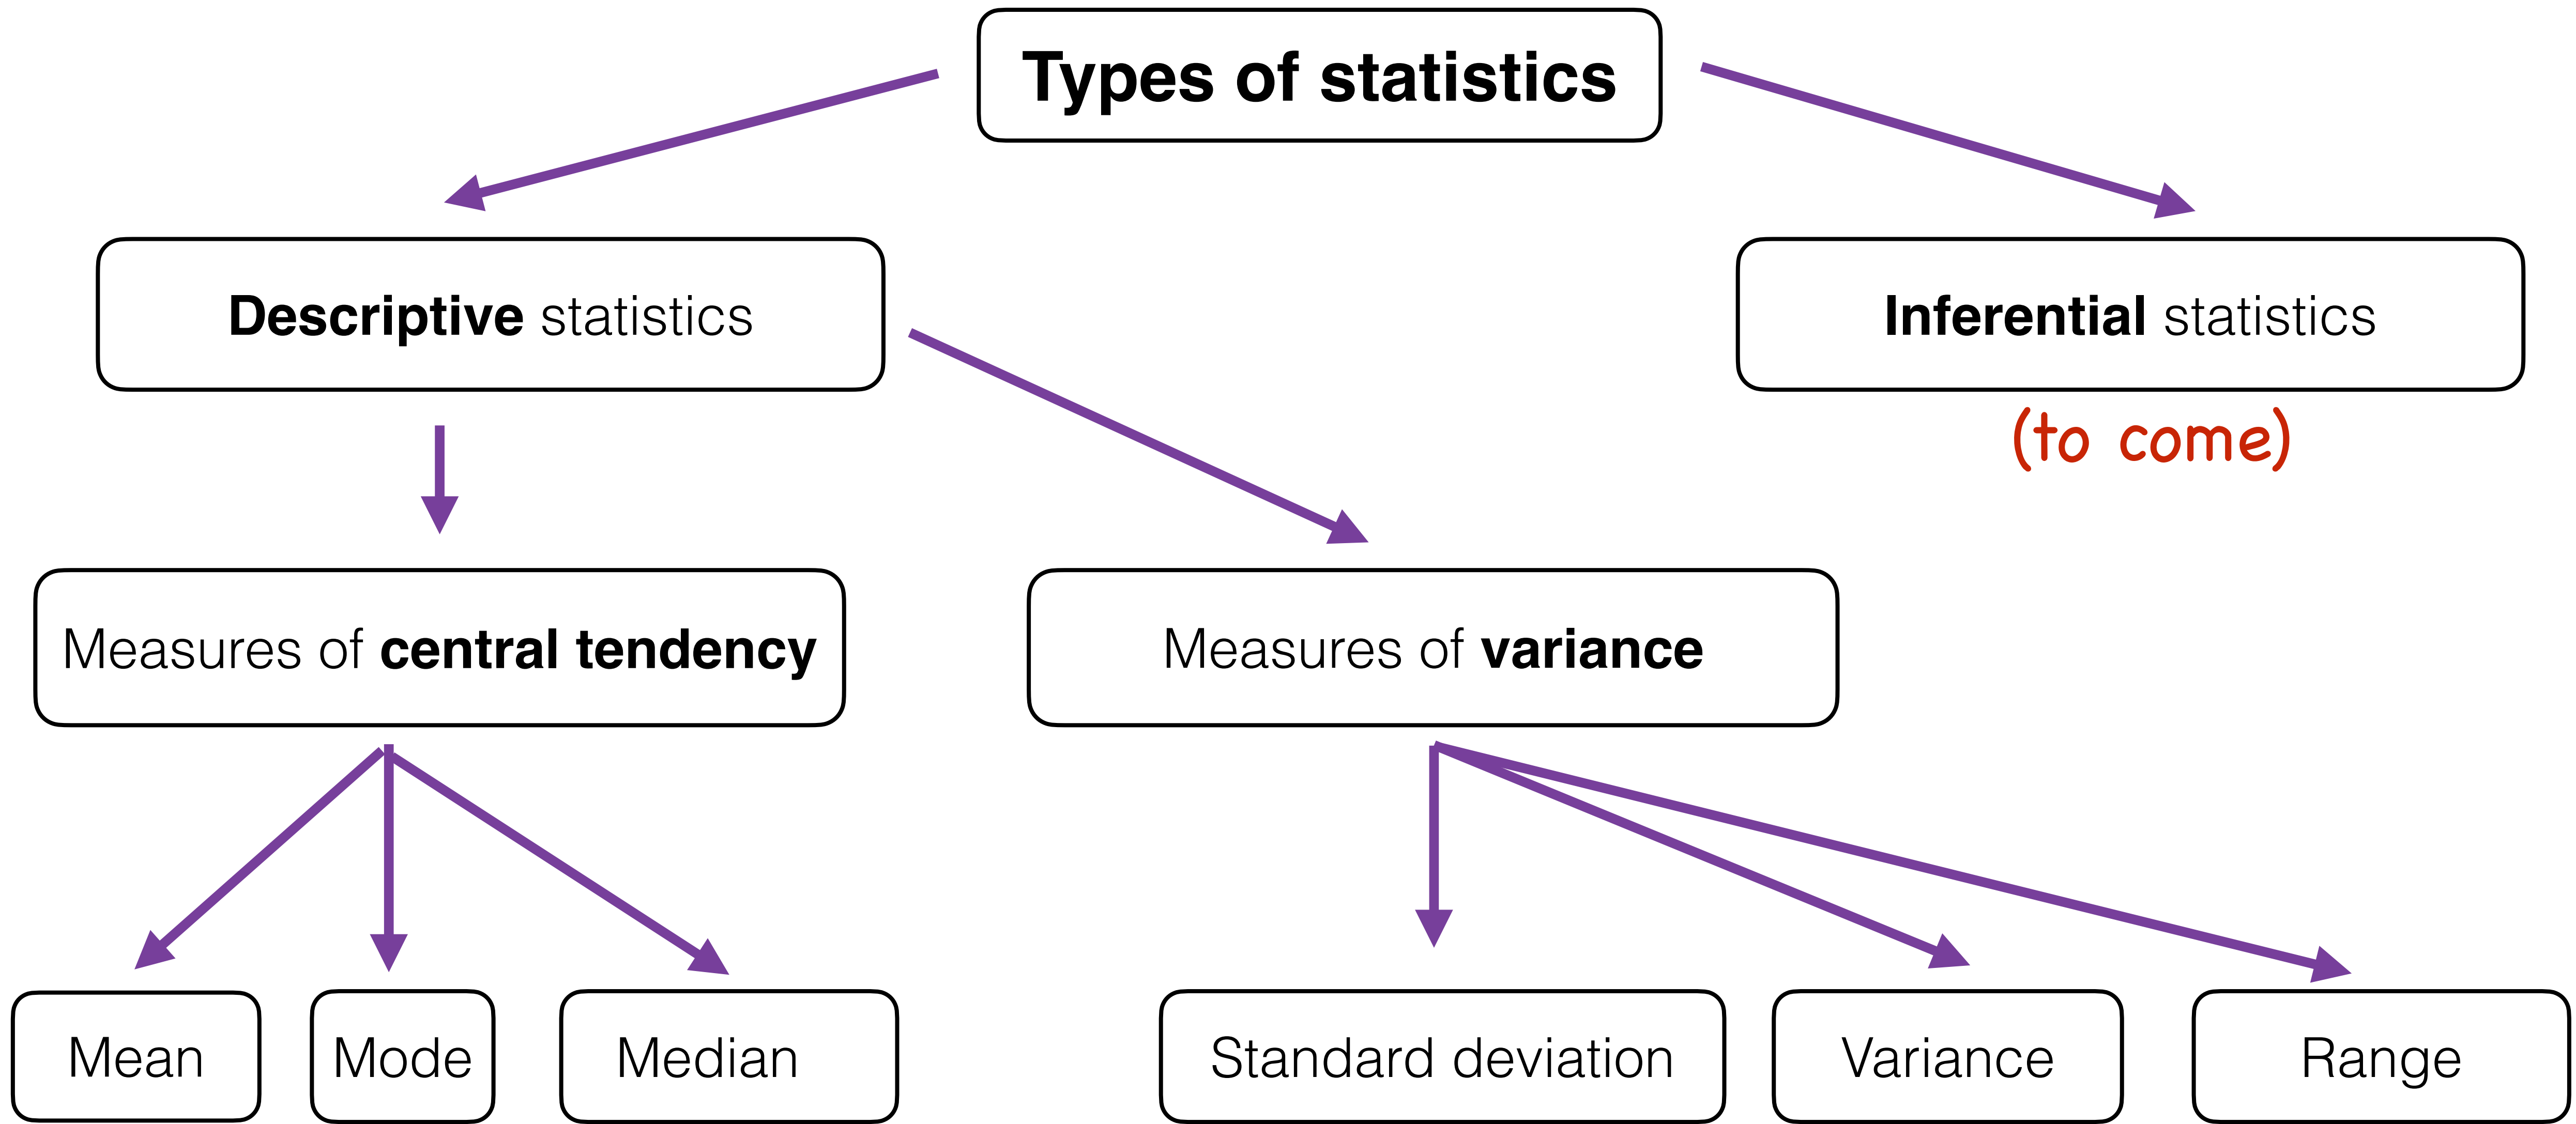

We are also interested in **outliers**.

The midpoint value is the **median**.

The average value is the **mean**.

The dispersion around the mean is described by the **standard deviation**.

Mean = sum of observations / number of observations

Desirable properties are that the **derivations** from the mean are zero-sum and the **least squares** property (to be discussed later).

A sample's **standard deviation** (sd) is given by $sd = \sqrt{variance(y)}$

Or more concretely:

$$sd = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n - 1}}$$

Where:

\bar{x} is your variable's mean.

x_i is an individual value.

n is the sample size.

Put simply, the average
difference between an
observation and the mean

With only the mean and standard deviation we can tell a lot about our observations if they approximate the normal distribution.

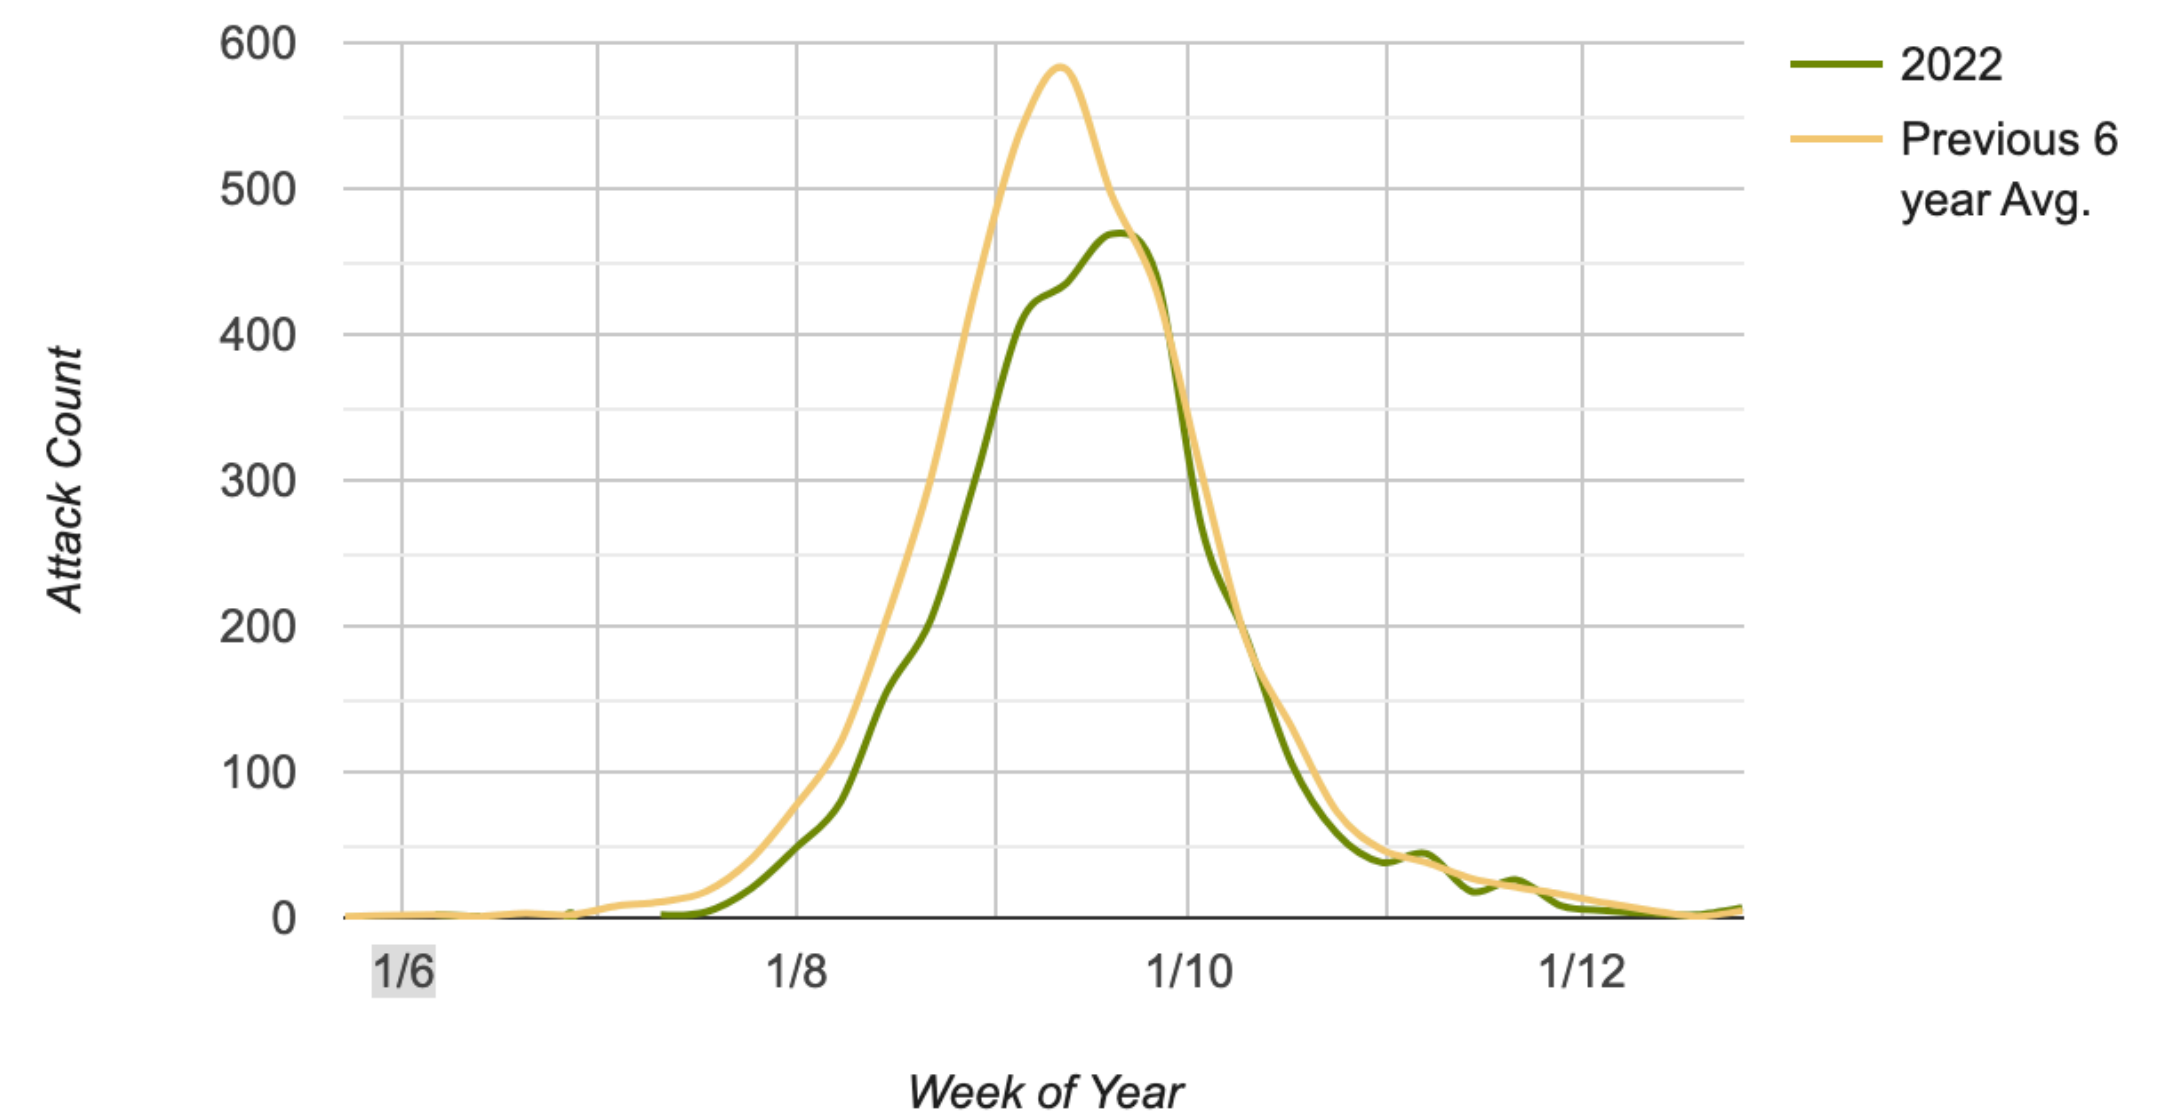

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}$$

Where:

μ = mean

σ = standard deviation

What can **descriptive inference** tell us that causal inference cannot?

What are the basic **descriptive statistics**?

Political scientists spend much more time thinking about **causal inference** and **data** analysis than they think about **conceptualising** and **describing** their causes (X's) and outcomes (Y's).

However, the former is of limited utility without the latter.
